

QUIZ

Write a C++ program based on the *following logic* below:

A number is already chosen in the program (for example: 7).

Create:

- one variable to store the chosen number,
- another variable to store the user's input,
- and an empty array (or list) to keep all the numbers entered by the user.

Use a while loop that continues running as long as the user's guess is not equal to the chosen number.

Inside the loop:

- ask the user to enter a number,
- store the value,
- immediately save the value into the array/list so that every attempt is recorded.

Then use if / else statements to compare the user's guess with the chosen number:

- if the guess is greater than the chosen number, display "Too high"
- if the guess is smaller, display "Too low"
- if the guess is equal, display "Correct"

After the loop finishes (meaning the correct number has been guessed), use a for loop to display all guesses stored in the array/list one by one.
